## ABOUT THIS MANUAL

This document describes the PLX PEX 8618BA-AIC4U4D, a Rapid Development Kit, from a hardware perspective. The contents of this document provide an accurate description of all aspects of this RDK board including a description of the major features and components, and details regarding the layout of the printed circuit board such as PCB mechanical outline, PCB stack-up, and component placement. This manual also includes complete schematics and bill of materials.

This Hardware Reference Manual is specific to the PEX 8618BA-AIC4U4D. In the event of a discrepancy between this Hardware Reference Manual and the PEX 8618 Data Book, please be sure to follow the instructions and guidelines as stated in the PEX 8618 Data Book when designing your systems.

## REVISION HISTORY

Date	Version	Comments
October 2008	1.0	Hardware Reference Manual initial release.
November 2009	1.1	Updated schematics and other miscellaneous edits
August 2010	1.2	Updated 2.7.3 to reflect support for SSC isolation

## 1. System Architecture

The PEX 8618BA-AIC4U4D is a PLX Rapid Development Kit intended primarily for use by PLX customers for silicon evaluation and design reference of the PEX 8618. The form factor is based on the PCI Express Card Electromechanical specification. The board is designed to work by plugging into a PCI Express compliant motherboard via a x8 PCIe card edge connector. Four Configuration Modules are used at two locations to provide the hardware routing flexibility needed to support the required port configurations that are used on this board. The PEX 8618BA-AIC4U4D board supports non-transparent operation through a PCIe cable. Probe mode is available through two MICTOR connectors and one 2x10 pin header. Figure 1 below shows board layout and placement of major components for the PEX 8618BA-AIC4U4D board.

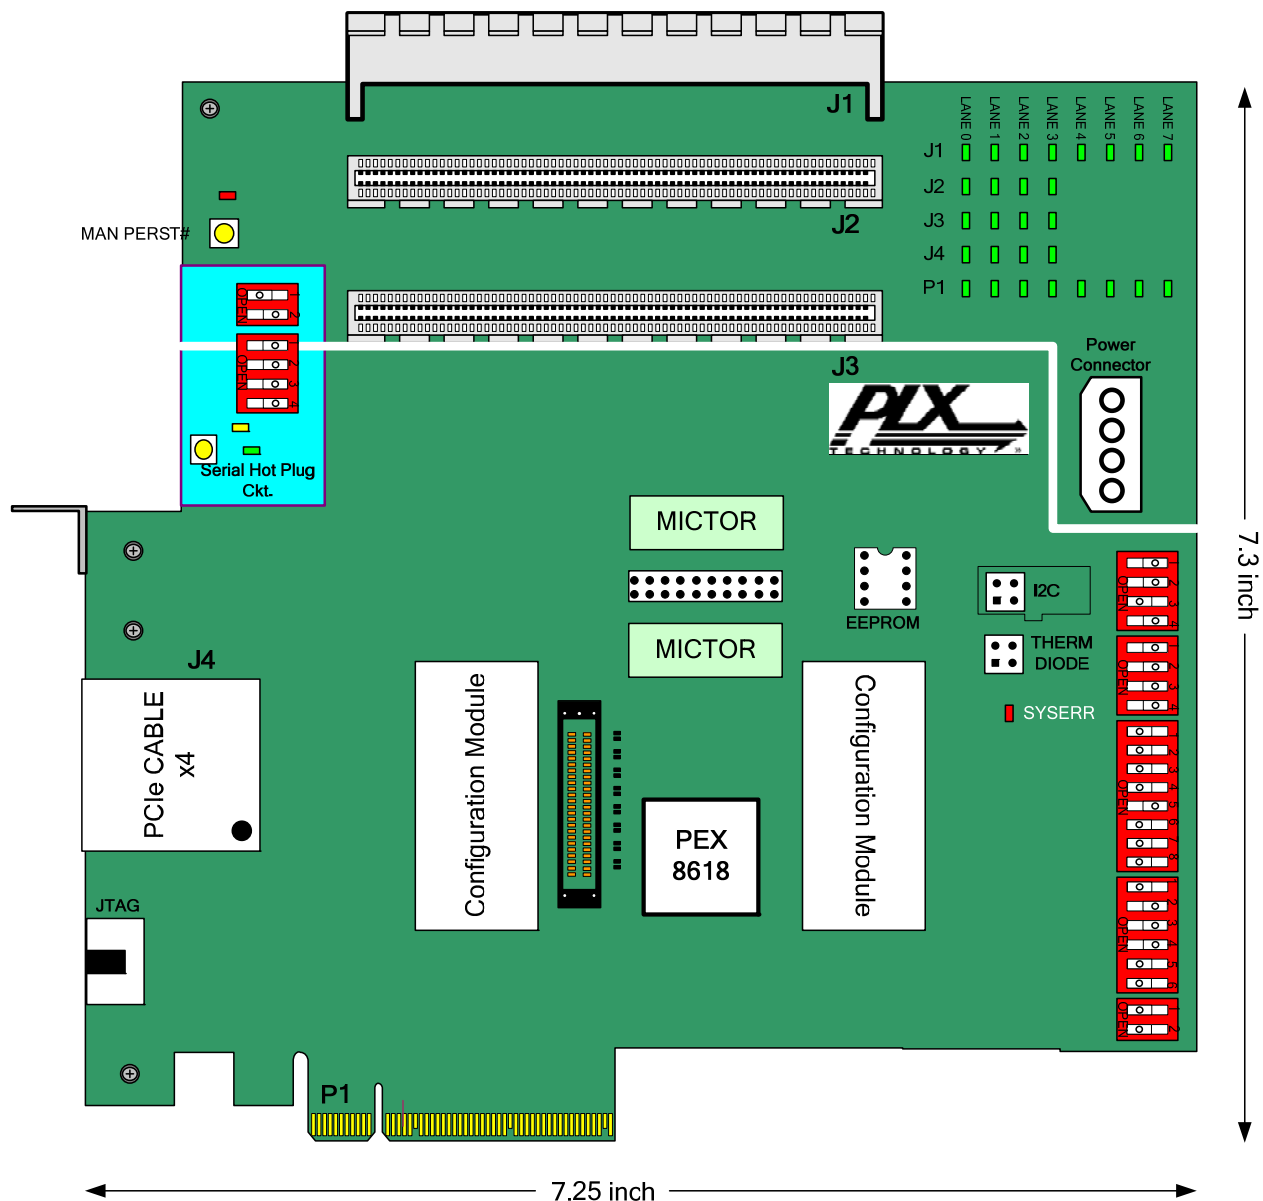

Figure 1. Component Placement for PEX 8618BA-AIC4U4D

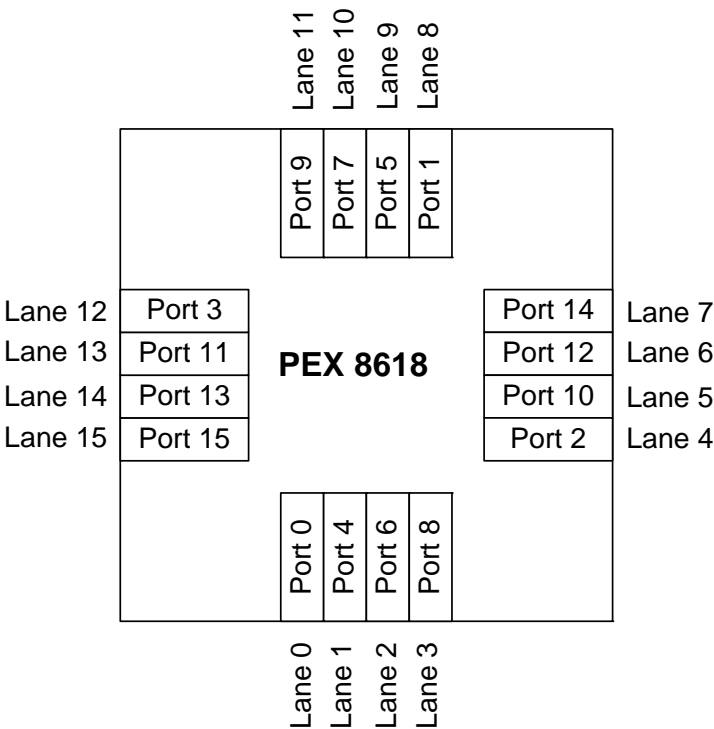

# 2. Hardware Architecture

## 2.1 PCI Express Port Configurations

The PEX 8618BA-AIC4U4D supports the PEX 8618 device: a 16-lane, 16-port, non-blocking PCI Express switch, which can support both transparent and non-transparent modes of operation. Section 2.1.1 below describes the port configurations that the PEX 8618BA-AIC4U4D supports, and how these configurations are set-up.

In addition to these configurations, Section 2.1.2 below describes how additional port configurations can be set-up through the use of x4 to x1x1x1x1 breakout boards. These boards may be purchased separately (part name Breakout Board 1111).

The PEX 8618 device lane numbering is shown in Figure 2 below.

**Figure 2. PCI Express Lane Numbering**

Lanes 8 through 15 pass through an Agilent soft touch midbus probe footprint in order to monitor PCIe traffic. Refer to the [Agilent Soft Touch Midbus Probe User's Guide](#) for further details of the headers. Lanes 0 through 3 are wired directly to card edge connector P1. Lanes 4 through 7 are routed to P1 or J3 by the Configuration Module on the right. Lanes 8 through 11 are routed to J1, J2, or J4 by the Configuration Module on the left. Lanes 12 through 15 are wired directly to J1. The board routing is such that connections to connectors J1 through J4 rely on lane reversal. Only connector P1 does not use lane reversal.

### 2.1.1 PEX 8618BA-AIC4U4D Port Configurations

The PEX 8618BA-AIC4U4D is designed to support the port configurations shown in [Table 1](#) below.

**Table 1. PEX 8618BA-AIC4U4D Configurations Supported**

Config	P1	J1	J2	J3	J4
x4x4x4x4 <b>Default Configuration</b>	X4 – Port 0	X4 – Port 3	X4 – Port 1	X4 – Port 2	
x8x4x4	X8 – Port 0	X4 – Port 3	X4 – Port 1		
x8x8	X8 – Port 0	X8 – Port 1			
x4x4x4-Cablex4	X4 – Port 0	X4 – Port 3		X4 – Port 2	X4 – Port 1
x8x4-Cablex4	X8 – Port 0	X4 – Port 3			X4 – Port 1

[Table 2](#), below, describes how the PEX 8618BA-AIC4U4D is hardwire configured to support these five configuration modes, and points to the appropriate Figure showing how the routing occurs.

**Table 2. PEX 8618BA-AIC4U4D Hardware Configurations**

Config	Left Config Module Used	Right Config Module Used	SW2 Settings	Routing Figure
x4x4x4x4 <b>Default Configuration</b>	-0107	-0108	LHLL	<a href="#">Figure 3</a>
x8x4x4	-0107	-0107	LHHH	<a href="#">Figure 4</a>
x8x8	-0110	-0107	HLLL	<a href="#">Figure 5</a>
x4x4x4-Cablex4	-0111	-0108	LHLL	<a href="#">Figure 6</a>
x8x4-Cablex4	-0111	-0107	LHHH	<a href="#">Figure 7</a>

### 2.1.2 Additional PEX 8618BA-AIC4U4D Port Configurations Using x4 to x1x1x1x1 Breakout Board(s)

Through the use of a x4 to x1x1x1x1 Breakout Board (purchased separately, part name Breakout Board 1111), the PEX 8618BA-AIC4U4D can support the additional port configurations shown in [Table 3](#) below.

**Table 3. Additional PEX 8618BA-AIC4U4D Port Configurations**

Config	P1	J1	J2	J3	J4
x8x4x1x1x1x1	x8 – Port 0	x1x1x1x1 – Ports 15, 13, 11, 3	x4 – Port 1		

[Table 4](#) below describes how the PEX 8618BA-AIC4U4D is hardwire configured to support these four additional configuration modes, and points to the appropriate Figure showing how the routing occurs.

**Table 4. PEX 8618BA-AIC4U4D Additional Hardware Configurations**

Config	Left Config Module Used	Right Config Module Used	Number of Breakout Boards	SW2 Settings	Routing Figure
x8x4x1x1x1x1	-0107	-0107	1	LHHL	<a href="#">Figure 8</a>

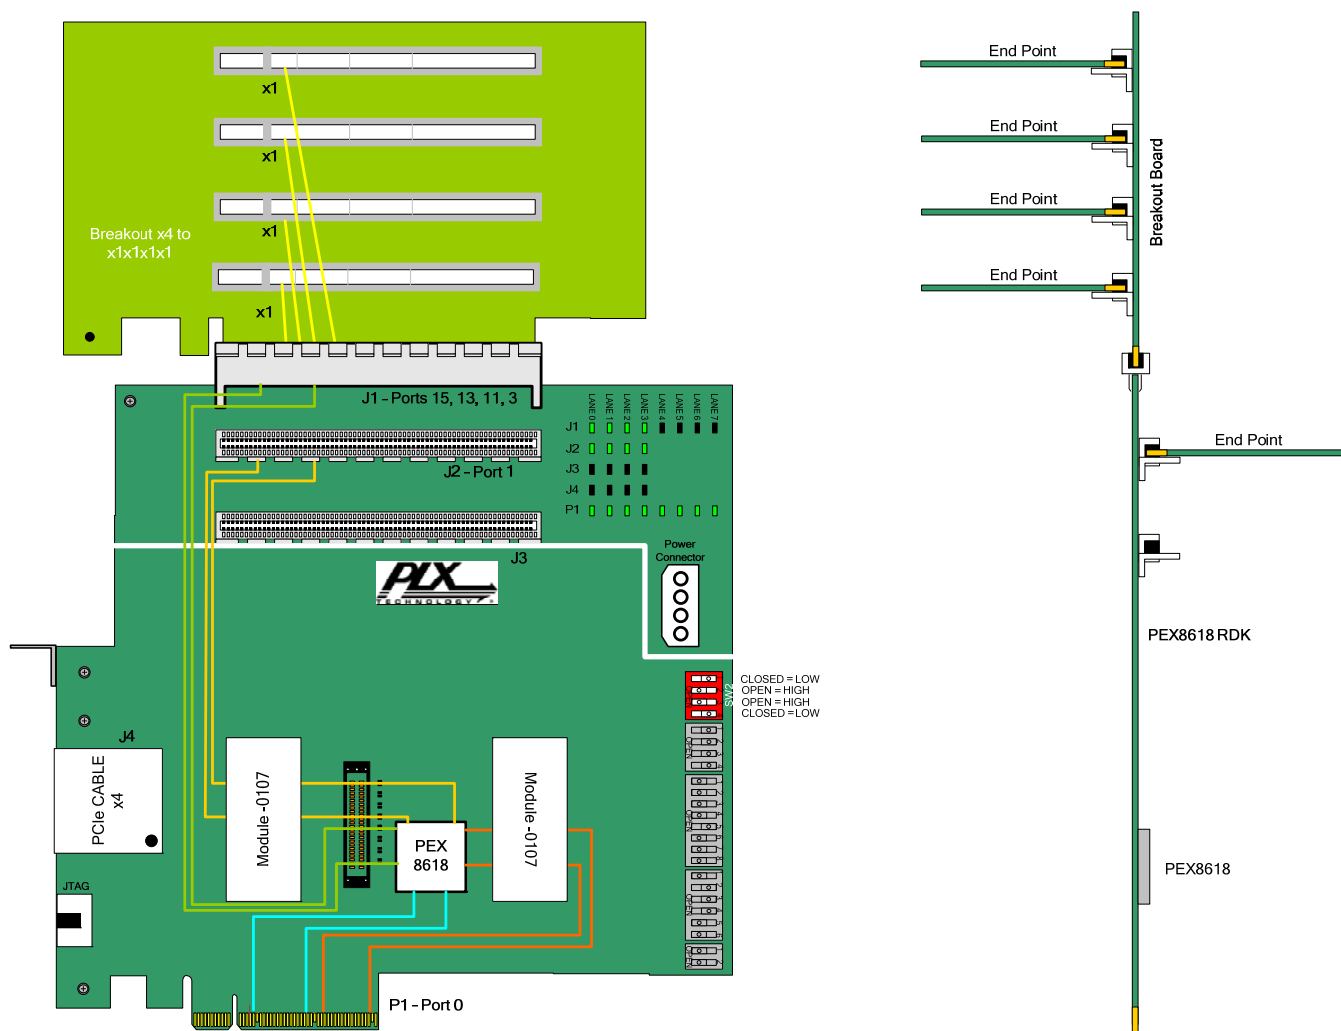

Figure 8. x8x4x1x1x1 Configuration

### 2.1.3 Configuration Modules

Two Configuration Modules are used on the board. The configuration modules consist of a 10x20 ball board-to-board high-speed connector, with one half of the connector mounted on the PEX 8618BA-AIC4U4D, and the other half mounted on a small 4-layer PCB that performs the re-mapping. There are no other components. Four different configuration modules are required. A 3-pin interface on the modules communicates their function to the board. The default configuration of the PEX 8618BA-AIC4U4D Rapid Development Kit provides one -0107 and one -0108 configuration module. Additional modules can be purchased separately.

### 2.1.4 x4 to x1x1x1x1 Breakout Board

The x4 to x1x1x1x1 Breakout Board is a board that can be purchased separately, part name **Breakout Board 1111**. This board takes four lanes from its male card edge connector and routes each lane to its own female slot connector. PCIe REFCLK from the male card edge connector goes to a 1:4 fan-out buffer, which is driven to each of the female slot connectors. PERST#, 3.3VAUX, and WAKE# are passed from the card edge connector to each of the female slot connectors.

## 2.2 PCI Express Cable Support

The PEX 8618BA-AIC4U4D is meant to demonstrate PCI Express cable usage. The cable connection, J4, is hardware configurable so that it can act as a downstream port. The board adheres to the downstream subsystem requirements as outlined in the [PCI Express External Cabling Specification Rev 1.0](#) for a x4 cable, with the following exceptions: none of the optional features are implemented, and CREFLCK is not dual 50 ohm terminated to ground. This means that only the lanes, and CPRSNT#, are implemented. Other side-band signals, such as CREFLCK and CPERST#, are not. The PCI Express cable connection can be used to demonstrate non-transparent operation to an NT host PC, see Section 2.3 for further details.

## 2.3 Non-Transparent Operation

The PEX 8618BA-AIC4U4D board is capable of routing Lanes 8 through 11 to a x4 PCI Express cable connector, J4. This, in conjunction with a cable adapter board, permits connection to a second computer to demonstrate non-transparent operation. There is a specific power-up sequence that must be followed. The host PC must be powered-up before the NT host PC. If the host PC is running spread-spectrum clocking, then SSC isolation must be enabled. The NT host PC cannot be running spread-spectrum clocking. If it is, then a second PEX 8618BA-AIC4U4D with SSC isolation enabled must be used in place of the cable adapter board in the NT host PC to provide clock isolation. The PEX\_NT\_RESET signal from the PEX 8618 device is brought out to a test point via.

*Note: Please refer to the PEX8618 Errata document for updates on the SSC isolation function.*

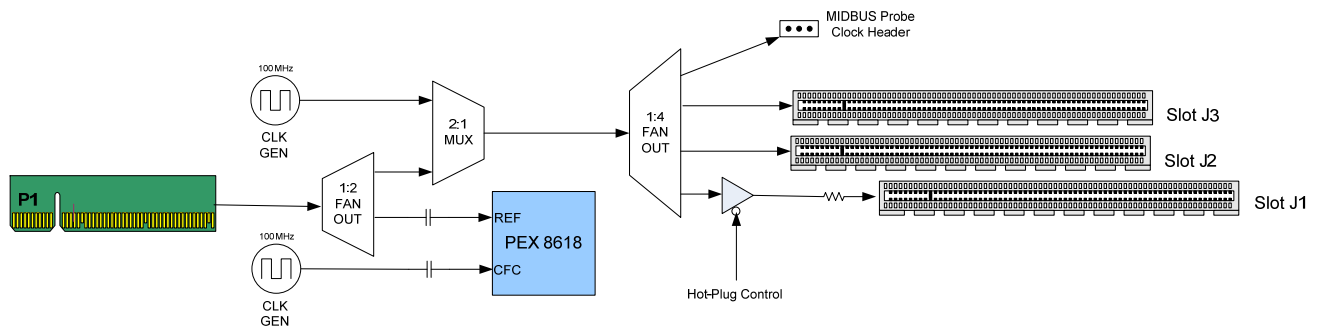

## 2.4 PCI Express Hot-Plug Circuitry

The PEX 8618 device supports Hot-Plug through a serial Hot-Plug interface brought out through I<sup>2</sup>C port 1. Only slot connector J1 supports Hot-Plug. The PEX 8618BA-AIC4U4D supports Hot-Plug to connector J1 via an IO expander IC. The lower 3 bits of the I<sup>2</sup>C address are pulled low through resistors to give a 7-bit I<sup>2</sup>C address to the IO expander of 38h. The two power rails to this slot (3.3VDC and 12VDC) are current limited to 5 amps. Hot-Plug control of this slot can be disabled by setting switch SW10-1 to CLOSED (LOW), so that this slot is always on. The MRL# signal is simulated by switch SW10-2. Switch block SW8 sends the Hot-Plug port address to the PEX 8618 device. The INTERLOCK signal from the PEX 8618 device is brought out to a test point via.

## 2.5 Reference Clock Circuitry

The PEX 8618BA-AIC4U4D has circuitry to support SSC isolation. Refer to the [PEX 8618BA Quick Start Hardware Design Guide](#) for details on how spread-spectrum clock isolation is implemented in the PEX 8618 device.

The RefClk from the host PC is brought onto the board via card edge connector P1. This clock is assumed to be spread-spectrum. This clock drives a 1:2 clock fan-out buffer. One of these fan-out clocks goes to the PEX 8618 device's PEX REFCLK input. The other fan-out clock goes to a 2:1 mux. The other input to this mux is from an onboard constant frequency clock generator. The output from this mux drives a 1:4 clock fan-out buffer, such as SpectraLinear's CY28400-2 device. The outputs from this fan-out buffer drive the downstream connectors. From the 1:4 fan-out buffer, one of these clocks is routed to connector J1 and can be enabled/disabled by the serial Hot-Plug circuit. If the Hot-Plug control is disabled, this clock is always enabled. Two of the clocks are routed to connectors J2 and J3 and are always enabled. The fourth clock is routed to a 3-pin header associated with using the midbus soft-touch probe. A second onboard constant frequency clock generator drives the PEX REFCLK CFC input to the PEX 8618 device. Refer to [Figure 9](#) below.

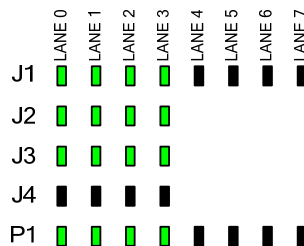

**Figure 9. PEX 8618BA-AIC4U4D Reference Clock Block Diagram**

The clock into the PEX 8618 device's PEX REFCLK input drives all SerDes when SSC ISOLATION is disabled. In this case the downstream slots must also be driven by this clock. When SSC ISOLATION is disabled, the on-board circuitry turns off the CFC clock into the 2:1 mux, and sets the 2:1 mux to pass the RefClk from P1 to the downstream connectors by way of the 1:4 fan-out buffer.

When using SSC ISOLATION, the clock into the PEX 8618 device's PEX REFCLK input only drives the SerDes for Port 0. In this case Port 0 CAN ONLY BE x4 or x8, and Port 0 must be an upstream port or an NT port. The clock into the PEX 8618 device's PEX REFCLK CFC input drives the remaining SerDes. The downstream slots must also be driven by this constant frequency clock. When SSC ISOLATION is enabled, the on-board circuitry turns off the SSC from the 1:2 fan-out buffer into the 2:1 mux, and sets the 2:1 mux to pass the CFC from the on-board generator to the downstream connectors by way of the 1:4 fan-out buffer.

## 2.6 Lane Status Indicator LEDs

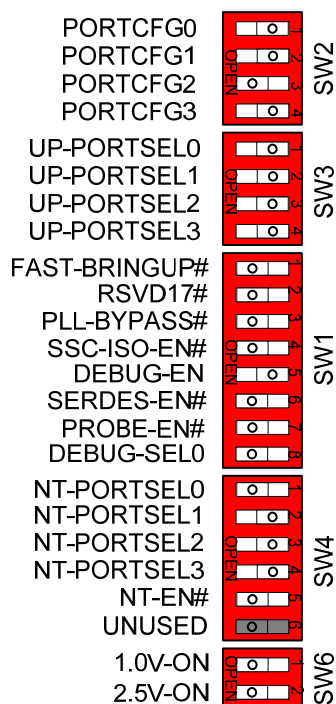

The status of each PCIe lane can be monitored by a bank of green LEDs driven by the PEX 8618 device's lane status balls. This bank of indicators are grouped in the upper right corner of the RDK board. Blinking indicates Gen 1 speeds, solid indicates Gen 2 speeds. Refer to [Figure 10](#) below.

**Figure 10. PEX 8618BA-AIC4U4D Lane Status LEDs**

## 2.7 Switches and Jumpers

The PEX 8618 has a number of strap pins which provide the capability to perform various types of hardware initialization without the use of software. Some strap pins are brought out to DIP switches, including the PORT\_CFG strap pins. When the DIP switch is CLOSED, the value is LOW. When the switch is OPEN, the value is HIGH. Other strap pins that are not used in typical situations are strapped using pull-up/pull-down resistors. Strap pins I2C\_ADDR[2:0] are pulled low, and STRAP\_TESTMODE[3:0] are pulled high, through resistors.

**Figure 11. Hardware Strap Configuration Switches**

### 2.7.1 SW2 – Port Configuration

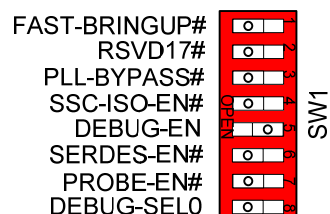

PORTCFG[3:0]	Port Configuration	Default RDK
LHLL	x4x4x4x4	Yes
LHHL	x8x4 and 4 x1	-
LHHH	x8x4x4	-
HLLL	x8x8	-
All Others	<i>Reserved</i>	-

### 2.7.2 SW3 – Upstream Port Select

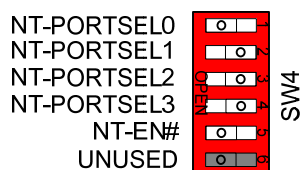

Default is Port 0. Upstream port and NT port cannot be the same port.

### 2.7.3 SW1 – Functional Strapping Selection

<b>FAST-BRINGUP#</b>	<i>Factory Test Only.</i> Keep HIGH(OPEN)
<b>RSVD17#</b>	<i>Factory Test Only.</i> Keep HIGH(OPEN)
<b>PLL-BYPASS#</b>	<i>Factory Test Only.</i> Keep HIGH(OPEN)
<b>SSC-ISO-EN#</b>	Default is HIGH(OPEN). LOW(CLOSED) Enables spread-spectrum clocking isolation. Refer to Section 2.5 for details.
<b>DEBUG-EN</b>	Default is LOW(CLOSED). HIGH(OPEN) isolates the debug signals from on-board circuitry (Lane Status LEDs, etc.) so they only go to the debug headers. Refer to Section 2.10 for details.
<b>SERDES-EN#</b>	LOW(CLOSED) Enables SerDes debug mode. If Enabled, DEBUG-EN needs to be HIGH(OPEN).
<b>PROBE-EN#</b>	LOW(CLOSED) Enables Probe debug mode. If Enabled, DEBUG-EN needs to be HIGH(OPEN).
<b>DEBUG-SEL0</b>	<i>Factory Test Only.</i> Keep HIGH(OPEN)

### 2.7.4 SW4 – Non-Transparent Port Select

Default is NT Port 1, with Non-Transparent disabled. Upstream port and NT port cannot be the same port. Location 6 on DIP Switch SW4 is unused.

### 2.7.5 SW6 – On-Board Voltage Generation Enable

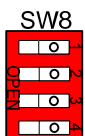

Default is all HIGH(OPEN). When LOW(CLOSED), these switches turn off the on-board voltage generation for the PEX 8618 device in order to use external voltage supplies to the PEX 8618 device for voltage margining and current measurement tests.

### 2.7.6 SW10 – Hot-Plug Control

<b>SHP EN</b>	Default is HIGH(OPEN). When HIGH(OPEN) the PEX 8618 controls the Hot-Plug slot. When LOW(CLOSED) the Hot-Plug slot is always turned on.
<b>MRL#</b>	Default is LOW(CLOSED). This switch mimics the Manual Retention Lever signal.

### 2.7.7 SW8 – Hot-Plug Slot Address

Default is all LOW(CLOSED). These switches transmit the Hot-Plug slot address back to the PEX 8618 device.

### 2.7.8 JP11 – 3.3 Vaux Jumper

Default is NOT installed. The PEX 8618BA-AIC4U4D is meant to support WAKE functionality. Therefore, 3.3 Vaux is routed from card edge connector P1 to the downstream slot connectors. However, some slots that the PEX 8618BA-AIC4U4D is plugged into may not support 3.3 Vaux, and some add-in cards require 3.3 Vaux. In this case this jumper is installed to route 3.3 VDC from the card edge connector P1 to 3.3 Vaux of the downstream slot connectors.

## 2.8 Power Circuitry

The PEX 8618BA-AIC4U4D is an add-in board. Power to the on-board circuitry is derived from PCIe card edge connector P1. Power to the PCIe slot connectors J1, J2, and J3 is from hard disk drive connector P2. A 4-pin, straight mount, HDD power connector is used.

Dedicated power rails supply the 1.0VDC and 2.5VDC voltages to the PEX 8618 device only. This permits accurate current draw measurements when operating in various port configurations and traffic levels. Test points are available to attach external power supplies to provide the 1.0VDC (TP1 for 1.0VDC, TP2 for GND) and 2.5VDC (TP3 for 2.5VDC, TP4 for GND). This permits current draw measurements and voltage margining of the PEX 8618 device voltages. When using external supplies, onboard voltage generators need to be disabled by switch SW6. Bi-color red/green LED indicators are used to indicate when 1.0VDC is within 5%, and 2.5VDC is within 10%.

Power to PCIe slot J1 can be controlled by the Hot-Plug circuit.

## 2.9 Reset Circuit

The PEX 8618BA-AIC4U4D accepts a PERST# from the host PC via card edge connector P1. This signal is OR'd with a manual reset circuit. The manual reset circuit consists of a pushbutton (SW7, upper left corner) that feeds into a reset timer. The reset timer monitors its power rail and reset input. If the reset input is low or the supply rail is out of range, the reset output is held. Once both conditions no longer exist, the reset output will de-assert after a programmable reset timeout period (capacitor adjustable, default value 128 msec). The OR'd reset signal goes to the PEX 8618 device's PEX\_PERST# input pin, and the downstream slots' PERST# connector pins. PERST# to Slot J1 can be controlled by the PEX 8618 device's Hot-Plug interface.

## 2.10 Debug Mode Interface

The PEX 8618BA-AIC4U4D supports the use of probe mode and SerDes debug mode through two MICTOR connectors and one 2x10 pin header. The MICTORs are high-speed connectors that deliver probe mode signals from the PEX 8618 device. The 2x10 pin header delivers selection signals to the PEX 8618 device. Probe mode signals are multiplexed onto other package balls that, in normal operation, deliver low speed signals for things like lane status. Table 5 provides a description of the signal mapping of the debug signals to the debug mode headers.

*Note: Inputs are marked in blue, outputs are marked in red.*

**Table 5. Signal Mapping of Debug Signals**

Ball Name	Probe Mode	SerDes Debug Mode	Connection
STRAP_NT_UPSTRM_PORTSEL2	stn_sel		SW4-pin3

Due to signal integrity concerns, the probe mode interface is placed near, and directly attached to, the PEX 8618 device. A CPLD provides isolation between the PEX 8618 device and the onboard circuitry that these signals would drive when the PEX 8618 device is in normal operation. When in probe mode, the CPLD blocks these signals from being propagated by setting switch SW1-pin5 (DEBUG-EN) to OPEN (HIGH). Please contact PLX when using the Probe Mode Interface.

## 2.11 Serial EEPROM Interface

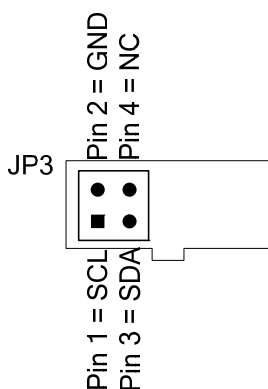

The PEX 8618BA-AIC4U4D provides a socketed Serial EEPROM. The contents of the serial EEPROM can be used to initialize the PEX 8618 device after power-on reset.

## 2.12 JTAG Interface

The PEX 8618BA-AIC4U4D has a dedicated JTAG header (JP2) to the PEX 8618 device. The header provides connections for TDI, TDO, TMS, TCK, TRST# and GND. This connector is right angle and accessible through the bulkhead bracket.

## 2.13 I<sup>2</sup>C Interface

The PEX 8618 device provides a two-wire I<sup>2</sup>C compatible slave mode interface with three bit addressing. Through this out-of-band channel, the users can read, write, and configure the PEX 8618 device internal registers, run internal output probe mode, monitor error counters, and monitor status. There is no “standard” I<sup>2</sup>C header pin arrangement; therefore, I<sup>2</sup>C header type and pin assignments are somewhat arbitrary. A 2x2 pin header is used with a silkscreen outline to represent how an Aardvark controller would connect. See [Figure 12](#) below. The upper 4 bits of the 7-bit I<sup>2</sup>C address have a default value of 0111. The lower 3 bits of the 7-bit I<sup>2</sup>C address are determined by external pull-up/pull-down resistors. The default I<sup>2</sup>C address provided by the 8618BA-AIC4U4D is 38h.

**Figure 12. I<sup>2</sup>C Interface Footprints**

## 2.14 FATAL\_ERR#, INTA#, PEX\_NT\_RESET#

The PEX 8618 device has a number of chip-specific side band signals that are intended for various uses. The FATAL\_ERR# output (legacy SERR# equivalent) is used to indicate that the PEX 8618 device detected a fatal unrecoverable error. The INTA# output is used to be compatible with PCI. The PEX\_NT\_RESET# output is used to indicate an in-band Reset from an NT host. These three signals are brought out to test point vias, so that a customer can access these pins. The FATAL\_ERR# signal also drives a red LED indicator. The INTA# signal also drives a yellow LED indicator.

# PEX 8618 Preliminary

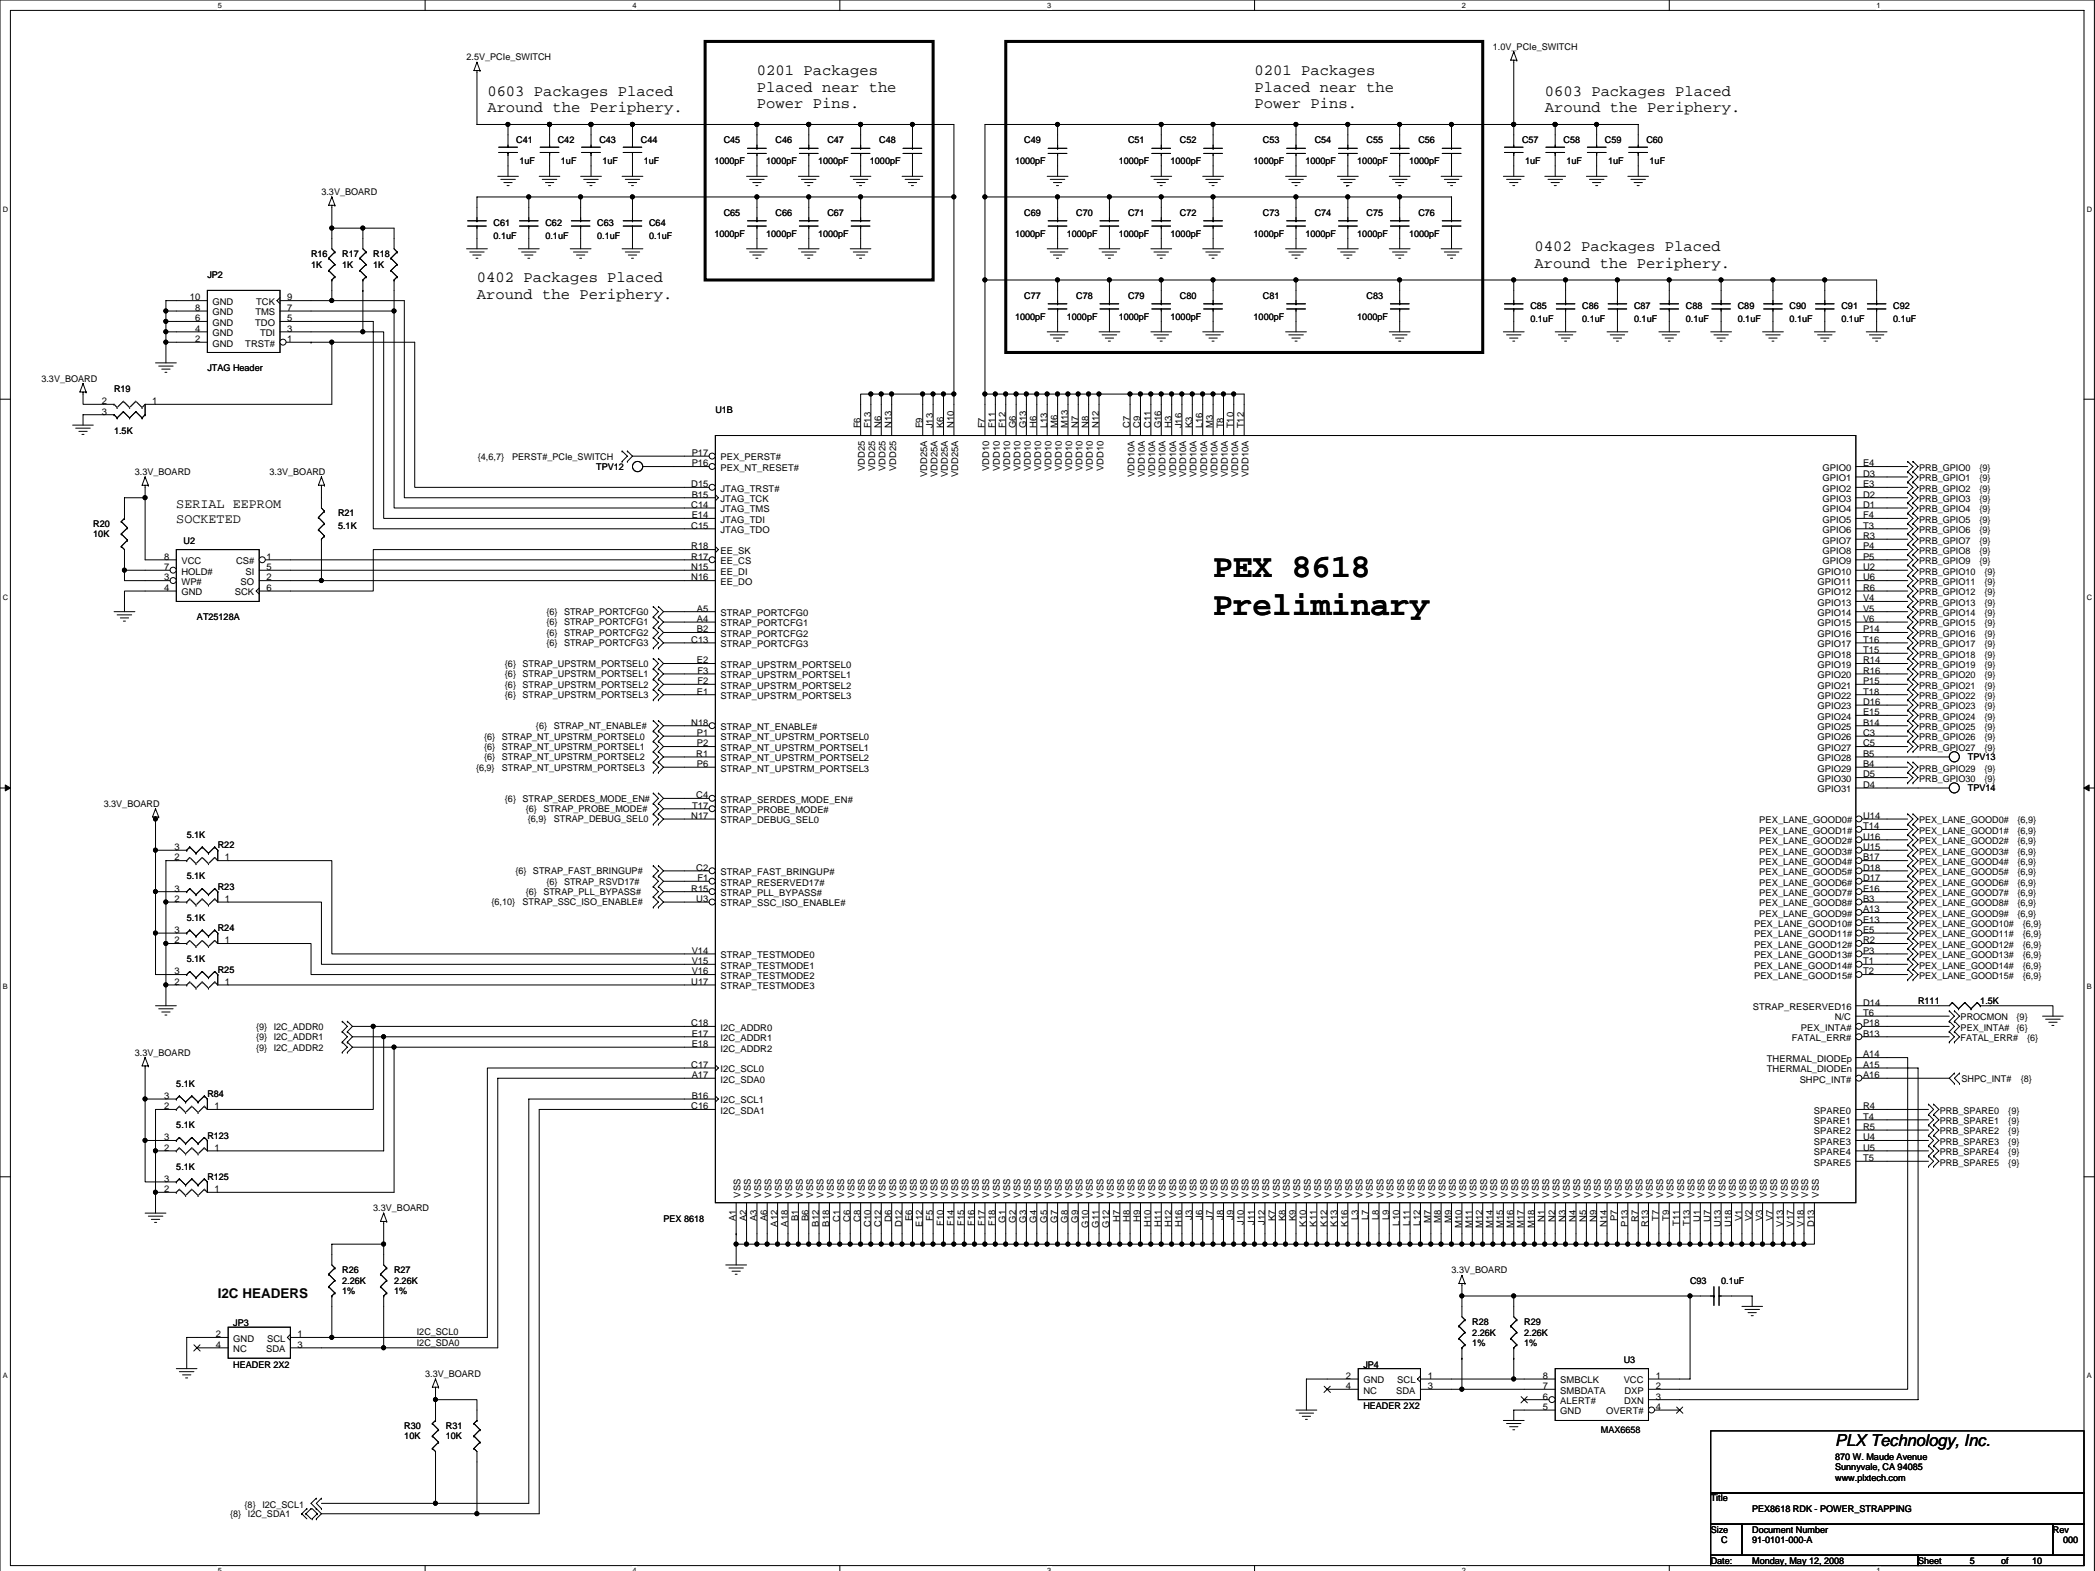

PLX Technology, Inc.  
870 W. Maude Avenue  
Sunnyvale, CA 94085  
www.plxtech.com

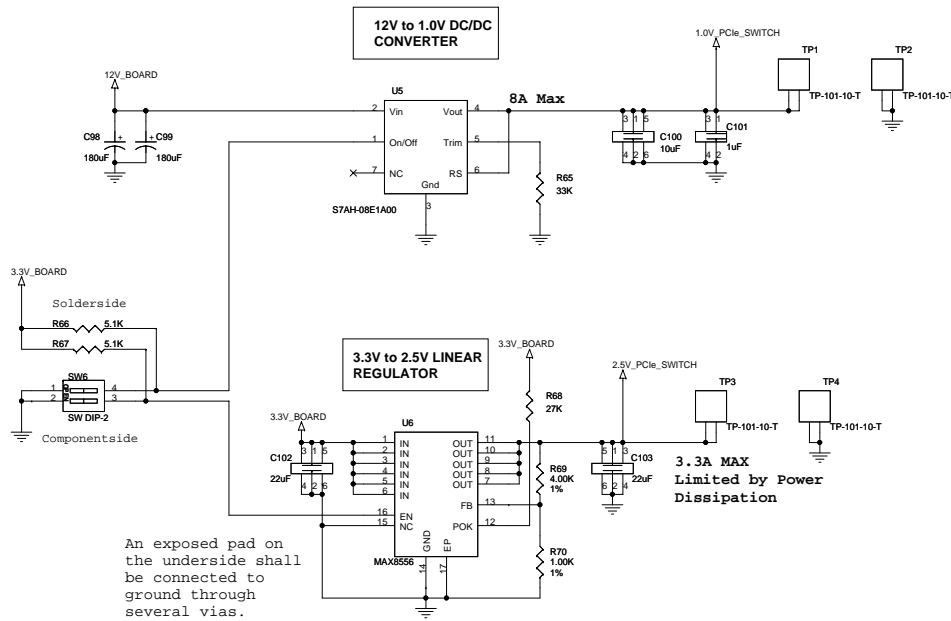

IF 3.3Vaux IS NOT AVAILABLE FROM EDGE CONNECTOR P1, BUT CARDS PLUGGED INTO THE DOWNSTREAM SLOTS REQUIRE IT, THEN INSTALL JUMPER JP11.

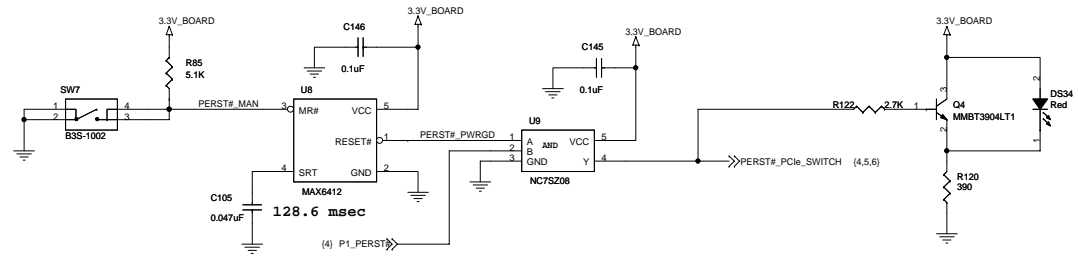

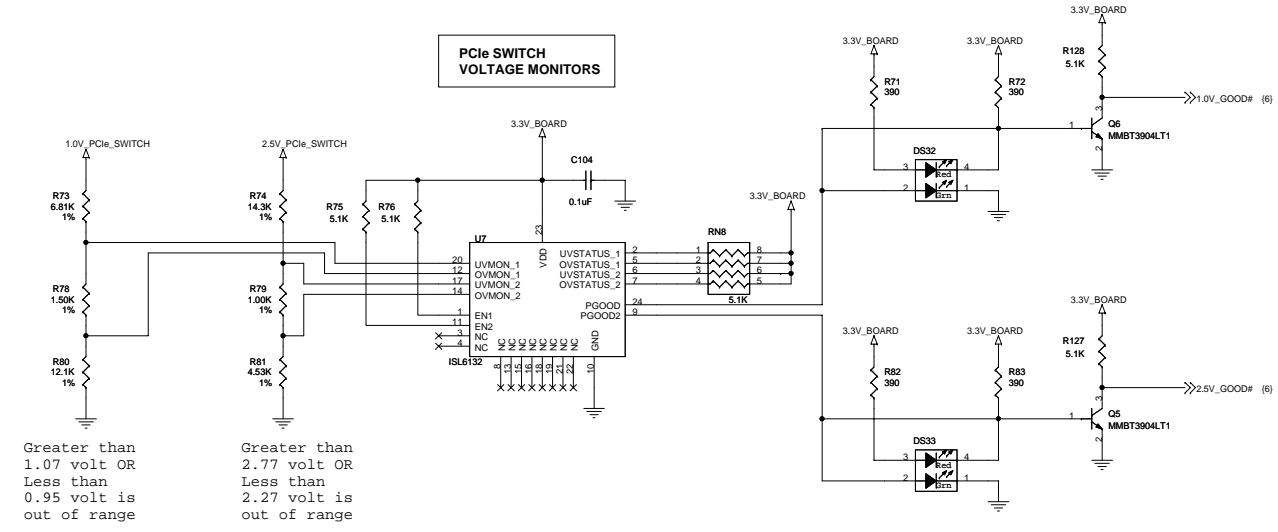

PLX Technology, Inc.  
8700 E. McDowell Avenue  
Sunnyvale, CA 94085  
www.plxtech.com

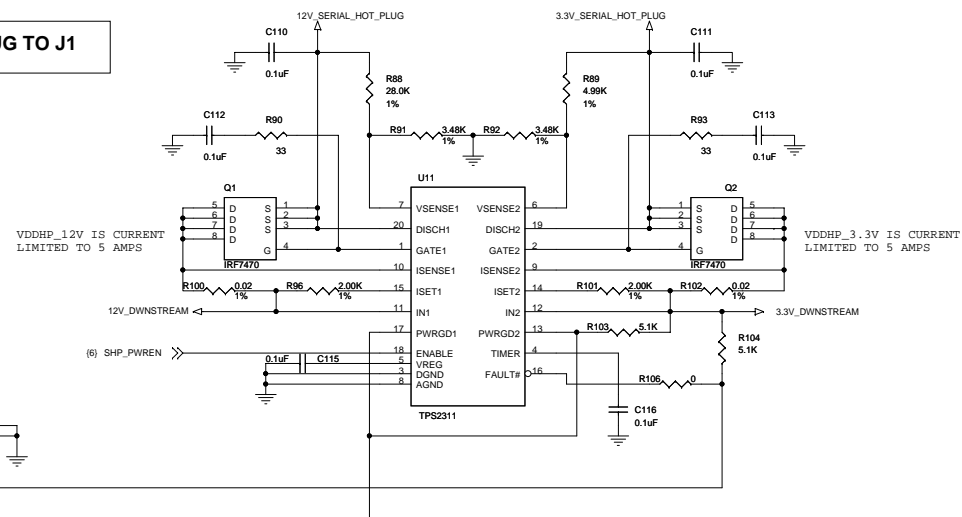

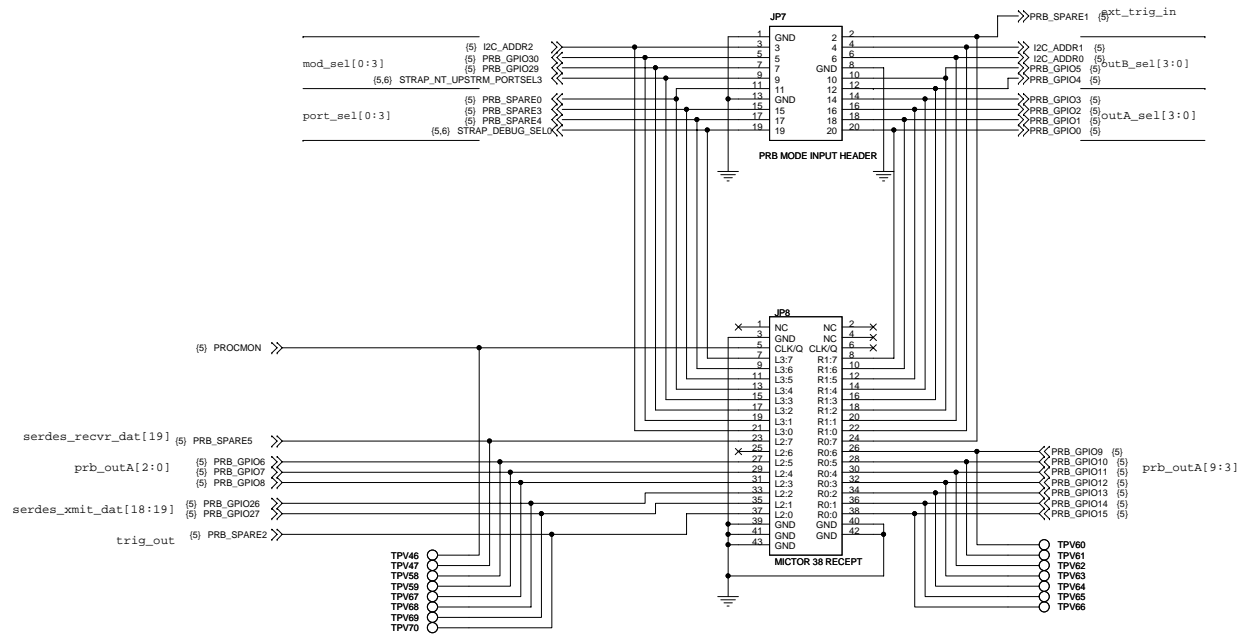

An exposed pad on the underside shall be connected to ground through several vias.
